A multidisciplinary approach for weather & climate

# Introduction

The objective is to provide some **recommendations** (and examples) for the **encoding of metadata** and data in a form suitable for archiving.

The aim is to be explicit (as possible), to provide: values for file/record specific attributes (and not for overall collections), richer metadata and conventions.

The **intention** is to be minimalist to allow downstream data **re-use beyond the original intent**, product development, scientific quality control and provision of long-term preservation.

This means that this recommendation is not intended to provide metadata to specific project, experiment or simulation, like attributes for data discovery, or special characteristics.

This recommendation is **based on CF-1.6 Convention Document** and the **Standard Name Table**.

The **encoding reference** used is the **netCDF-classic data model**, but extension to other encoding formats should be possible.

A multidisciplinary approach for weather & climate

# **Encoding formt**

The **encoding reference** used is the **netCDF-classic data model**, but extension to other encoding formats should be possible:

When netCDF is used the recommendation is to use the **netCDF-4 classic model format** which follows the netCDF classic data model, but provides features from the **HDF5 storage layer**:

- Uses classic API for compatibility
- Uses netCDF-4/HDF5 storage for compression, chunking, performance
- To use, just recompile, relink

netCDF-3 (classic)

netCDF-4 classic model

NetCDF-4 (enhanced model)

Metadata

- A multidisciplinary approach for weather & climate
- Metadata is data that provides information about other data
- Distinct types of metadata exist:
  - descriptive metadata describes a resource for purposes such as discovery and identification. It can include elements such as title, abstract, author, and keywords.
  - structural metadata is about containers of data and indicates how compound objects are put together, for example, how pages are ordered to form chapters. It describes the types, versions, relationships and other characteristics of digital materials.
- This recommendation it's about structural metadata enabling users
  and tools to identify comparable data and facilitating the development
  of software to store, extract, process, analyze and display.

A multidisciplinary approach for weather & climate

# **Data Fields**

A data field (DF) is defined as a combination of several data variables.

In general, a data field may span data variables in more than one file object: i.e. different ranges of a time coordinate.

Rules for aggregating data variables from one or several files objects into a single data field are needed but are not defined by CF. (but some exist)

The assumption is that each DF is independent.

**But** data stored in netCDF files are **often not independent**, because **coordinate** variables are **shared between them**.

- This sharing is a means of saving disk space, and any software should be able to alter any DF without altering any other DF.
- If a given coordinate of a DF is altered this should not affect other DF's in the same file.

For example, daily near-surface minimum temperature could share longitude and latitude coordinates variables with 6 hourly instantaneous temperature at 500mb pressure level, but different temporal and vertical coordinate variables should be used.

A test on the equality, and/or equivalence, of coordinates between different DF's should be made when attempting to merge DF from different files or records.

A multidisciplinary approach for weather & climate

# **Data Fields**

#### A DF may have:

- 1) 0..N domain indexes: each domain coordinate has a size (an integer value greater than zero).
- 2) 1 data array whose shape is been determined by the domain indexes. All elements on the data array must be of the same data type (numeric, char or string).
- 3) A collection of **domain coordinates**: A domain coordinate construct indicates the physical meaning and locations of the cells for a unique **domain indexes** of the field.
- 4) A collection of **auxiliary coordinates**: An auxiliary coordinate provides auxiliary information for interpreting the cells of an ordered list of one or more **domain coordinate** of the field.
- 5) A collection of **cell-measures**: A cell measure provides information about the size, shape or location of the cells (n-dimensional in general) defined by an ordered list of one or more domain coordinates of the DF.
- 6) An ordered collection of **cell-methods**: A cell methods describes how the data values represent variation of the quantity within cells. The methods are not necessary commutative, therefore it is an ordered list of methods.
- 7) A Coordinate (reference) systems: A coordinate system relates the field's coordinate values to locations in a topological space. When reference datum are provided (i.e. geodetic datums), a coordinate reference system could be transform to spatio-temporal locations in real world.
- 8) Other **properties** which represents metadata about the DF. Not all attributes in a netCDF file are properties in this sense. Some of these can be **global attributes** in a netCDF file. It is assumed that global attribute is **also an attribute of every data variable**, although it is **superseded** if the data variable has its **own attribute** with an identical name.
- 9) Ancillary fields to identify fields which provide additional metadata (i.e. QA of the data),

The domain axes, domain coordinates, auxiliary coordinates, cell measures, and cell method describe the domain in which the DF resides.

A multidisciplinary approach for weather & climate

# Coordinate systems

**Explicit** list of **domain coordinates** must be provided by **t**he **coordinates** attribute on data variable.

The coordinates define the provides the coordinate system

Identification of a **coordinate type** by its units alone is complicated, the **standard** name attribute provides a direct identification.

Additionally, to identify generic spatial and/or temporal coordinates the use of the attribute axis may be added to a coordinate-variable and given one of the values X, Y, Z or T.

The values of a coordinate are the locations of the boundaries between cells. The bounds attribute attached to coordinate variable indicates the variable with those values.

The values on coordinate variable are labels for cell locations

The dimensions on coordinates variables must comply with some rules wrt dimensions on data variable.

A multidisciplinary approach for weather & climate

# Coordinate reference Systems Regular longitude and latitude

```
netcdf regular latitude longitude grid {
  //global attributes:
    :Conventions = "CF-1.6";
  dimensions:
    latitude = 180 ;
    longitude = 360 ;
  variables:
    double mslp(latitude, longitude);
      mslp:standard name = "air pressure at sea level" ;
      mslp:units = "Pa" ;
     mslp:grid mapping = "hcrs" ;
      mslp:coordinates = "latitude longitude" ;
    double latitude(latitude) ;
      latitude:standard name = "latitude";
      latitude:units = "degrees north" ;
      latitude:axis = "Y" ;
    double longitude (longitude) ;
      longitude:standard name = "longitude" ;
      longitude:units = "degrees east" ;
      longitude:axis = "X" ;
    char hcrs ;
      hcrs:grid mapping name = "latitude longitude" ;
```

A multidisciplinary approach for weather & climate

# Coordinate Systems Vertical

Variables representing dimensional height or depth axes must always explicitly include the units attribute; there is no default value for this attribute. If the units attribute value is a valid pressure unit the default value of the positive attribute is down.

A vertical coordinate will be identifiable by:

- units of pressure; and/or
- the presence of the positive attribute with a value of up or down (case insensitive); and/or
- by providing the standard\_name attribute with an appropriate value; and/or
- the axis attribute with the value Z.

A multidisciplinary approach for weather & climate

```
netcdf near-surface {
  //global attributes:
    :Conventions = "CF-1.6";
  dimensions:
    latitude = 180 ;
    longitude = 360;
  variables:

```

# Isobaric levels

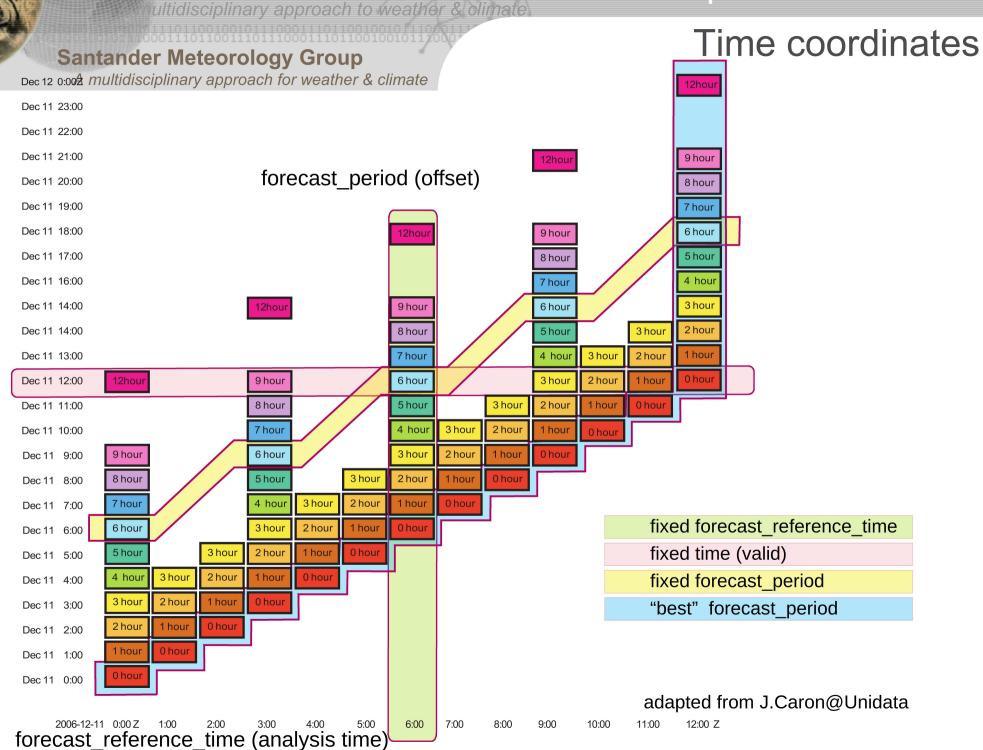

A multidisciplinary approach for weather & climate

# Time coordinates

# The CF standard name table defines:

- forecast\_reference\_time: The forecast reference time in NWP is the "data time", i.e. the time of the analysis from which the forecast was made. It is not the time for which the forecast is valid; the standard name of time should be used for that time
- forecast\_period: Forecast period is the time interval between the forecast reference time and the validity time. A period is an interval of time, or the time-period of an oscillation
- time: The valid time is the time for which the forecast or observation is valid

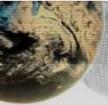

It is recommended that the calendar be specified by the attribute calendar which is assigned to absolute time coordinates (i.e. time and forecast\_reference\_time).

A multidisciplinary approach for weather & climate

# Time coordinates

```
netcdf valid time {
  //global attributes:
    :Conventions = "CF-1.6";
  dimensions:
    lat = 180 :
    lon = 360 ;
  variables:
    double mslp(latitude, longitude);
      mslp:standard name = "air pressure at sea level" ;
      mslp:units = "Pa" ;
     mslp:grid mapping = "hcrs";
      mslp:coordinates = "time fcstperiod reftime lat lon";
    double time;
      time:standard name = "time";
      time:units = "hours since 2016-10-26T00:00:00Z";
      time:calendar = "gregorian";
    double fcstperiod;
      fcstperiod:standard name = "forecast period";
      fcstperiod:units = "hours";
    double reftime;
      reftime:standard name = "forecast reference time";
      reftime:units = "hours since 2016-10-26T00:00:00Z";
      reftime:calendar = "gregorian";
    double lat(lat);
      lat:standard name = "latitude" ;
     lat:units = "degrees north" ;
     lat:axis = "Y" ;
    double lon(lon);
      lon:standard name = "longitude" ;
      lon:units = "degrees east";
     lon:axis = "X";
    char hcrs;
      hcrs:grid mapping name = "latitude longitude" ;
  data:
    reftime = 0.0;
    fcstperiod = 6.0;
    time = 6.0;
```

A multidisciplinary approach for weather & climate

# Discrete coordinates

The spatio-temporal coordinates and other geophysical quantities may likewise serve as **continuous coordinates**, for instance density, temperature or radiation wavelength.

But there is a need for coordinates which indicate either an **ordered list** or an **unordered collection**, and does not correspond to any continuous quantity variable.

Such coordinate may be called **discrete coordinate**.

For instance members of a ensemble may be defined as a realization coordinate it is been indicated by providing the standard name attribute with value realization,

realization: The term "realization" is used to label a dimension that can be thought of as a statistical sample, e.g., labeling members of a model ensemble.

A multidisciplinary approach for weather & climate

```
netcdf realization {
 //global attributes:
    :Conventions = "CF-1.6";
  dimensions:
    latitude = 180 ;
   longitude = 360;
   str31 = 31; //auxiliary dimension for string variables
 variables:
   double mslp(latitude, longitude) ;
      mslp:standard name = "air pressure at sea level" ;
      mslp:units = "Pa" ;
     mslp:grid mapping = "hcrs" ;
     mslp:coordinates = "realization reftime latitude longitude" ;
    char realization(str31);
      realization:standard name = "realization";
      realization:units = "1";
      realization:axis = "E";
    double reftime;
      reftime:standard name = "forecast reference time";
      reftime:units = "hours since 2016-10-26T00:00:00Z";
      reftime:calendar = "gregorian";
      reftime:axis = "T";
    double latitude (latitude) ;
      latitude:standard name = "latitude" ;
      latitude:units = "degrees north";
     latitude:axis = "Y" ;
   double longitude(longitude);
      longitude:standard name = "longitude" ;
      longitude:units = "degrees east";
     longitude:axis = "X" ;
    char hcrs :
      hcrs:grid_mapping_name = "latitude_longitude" ;
  data:
    reftime = 0.0:
    realization = "member1" ;
```

# Ensemble members

realization: The term realization is used to label a dimension that can be thought of as a statistical sample, e.g., labeling members of a model ensemble.

source: An auxiliary coordinate variable with a standard name of source contains string values [...] were model-generated, source should name the model and its version, as specifically as could be useful. [...] The use of source as the standard name for an auxiliary coordinate variable permits the aggregation of data from multiple sources within a single data file.

institution: An auxiliary coordinate variable with a standard name of *institution* contains string values which specify where the original data, with which the coordinate variable is associated, were produced. The use of *institution* as the standard name for an auxiliary coordinate variable permits the aggregation of data from multiple institutions within a single data file.

A multidisciplinary approach for weather & climate

# Cell aggregations

When data does not represent the **point values** of a field, but instead represents some characteristic of the **field within cells** of finite "volume", a complete description of the variable should include metadata that describes the domain or extent of each cell, and the characteristic of the field that the cell values represent.

- cell\_measures attribute represents information about the size, shape or location of the cells that cannot be deduced from the coordinates.
- cell\_methods attribute describe the characteristic of a field that is represented by cell values:

```
cell_methods="time: mean (interval: 1 day) longitude:
maximum (interval: 1 degree north)"
```

A multidisciplinary approach for weather & climate

```
netcdf daily maximum near-surface temperature {
 //global attributes:
    :Conventions = "CF-1.6";
  dimensions:
    latitude = 180 ;
   longitude = 360 ;
   bnds = 2:
 variables:
    double tasmax(latitude, longitude);
      tasmax:standard name = "air temperature" ;
      tasmax:units = "K";
      tasmax:grid mapping = "hcrs";
      tasmax:coordinates = "fp rt time height latitude longitude";
      tasmax:cell methods = "fp: maximum (interval: 1 hour)";
    double time:
      time:standard name = "time";
      time:units = "hours since 2016-10-26T00:00:00Z";
      time:calendar = "gregorian";
    double fp;

A multidisciplinary approach for weather & climate

# Summary

The objective is to provide some **recommendations** (and examples) for the **encoding of metadata** and data in a form suitable for archiving.

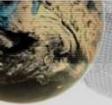

The aim is to be explicit (as possible), to provide: values for file/record specific attributes (and not for overall collections), richer metadata and conventions. Description metadata and provenance it's another key aspect

The **intention** is to be minimalist to allow downstream data **re-use beyond the original intent**, product development, scientific quality control and provision of long-term preservation. Library of tools will be required.

This means that this recommendation is not intended to provide metadata to specific project, experiment or simulation, like attributes for data discovery, or special characteristics. Each project/experiment should define its own Data Management Plan (i.e. guide for C3S seasonal data providers).

This recommendation is **based on CF-1.6 Convention Document** and the **Standard Name Table**. The CF it's community driven. This summer next version of CF-1.7.

The **encoding reference** used is the **netCDF-classic data model**, but extension to other encoding formats should be possible. D. Hassell et al. (2017). "A CF data model and implementation". To be appear in Geosci. Model Dev.
