Outline

Clouds and Precipitation: From models to forecasting

This seminar will (hopefully!) help you to ...

- describe how cloud and precipitation is represented in the ECMWF global model.
- recognise some of the strengths and weaknesses of the forecast cloud/precipitation.
- interpret cloud and precipitation related forecast products.
- learn about recent developments from a forecast users perspective ...

1. How are cloud and precipitation represented in the ECMWF model?

Parameterized processes in the ECMWF model

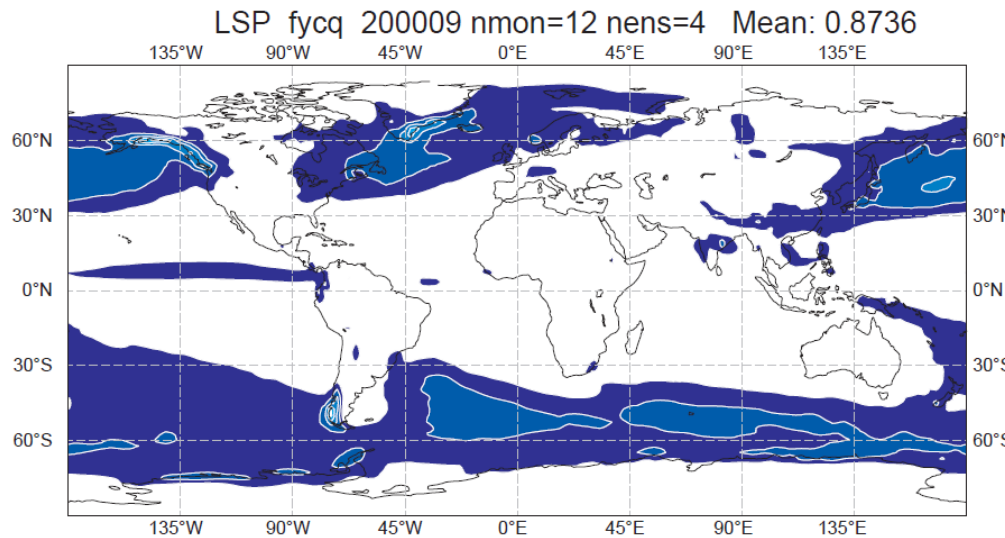

Convective and stratiform precipitation and clouds

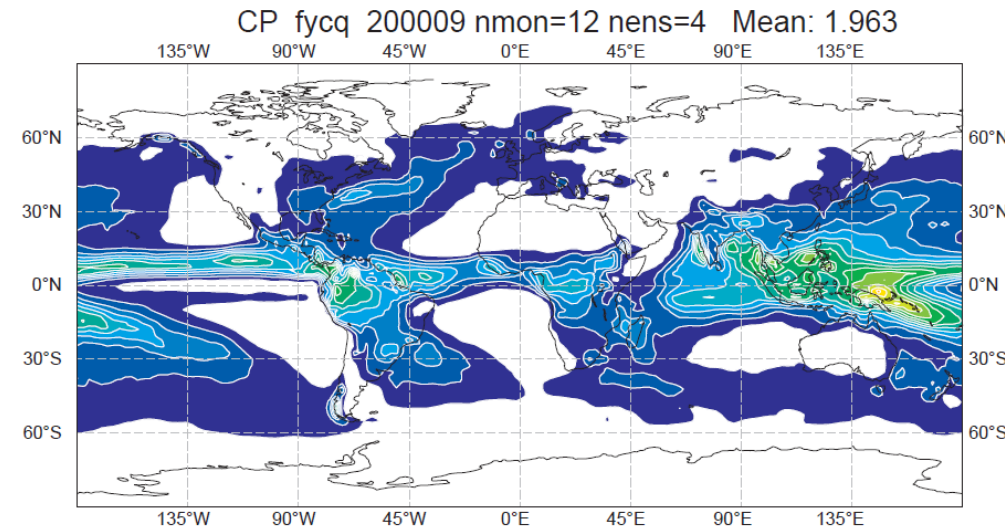

Global annual mean surface precipitation LSP/CP (S Cy40r1)

Stratiform
(large-scale)
surface precip
(LSP)

Convective
surface precip
(CP)

- This is for low resolution T159, but not too different for higher resolutions
- CP is ~2/3 of global precipitation
- but LSP dominant or similar to CP in extratropics

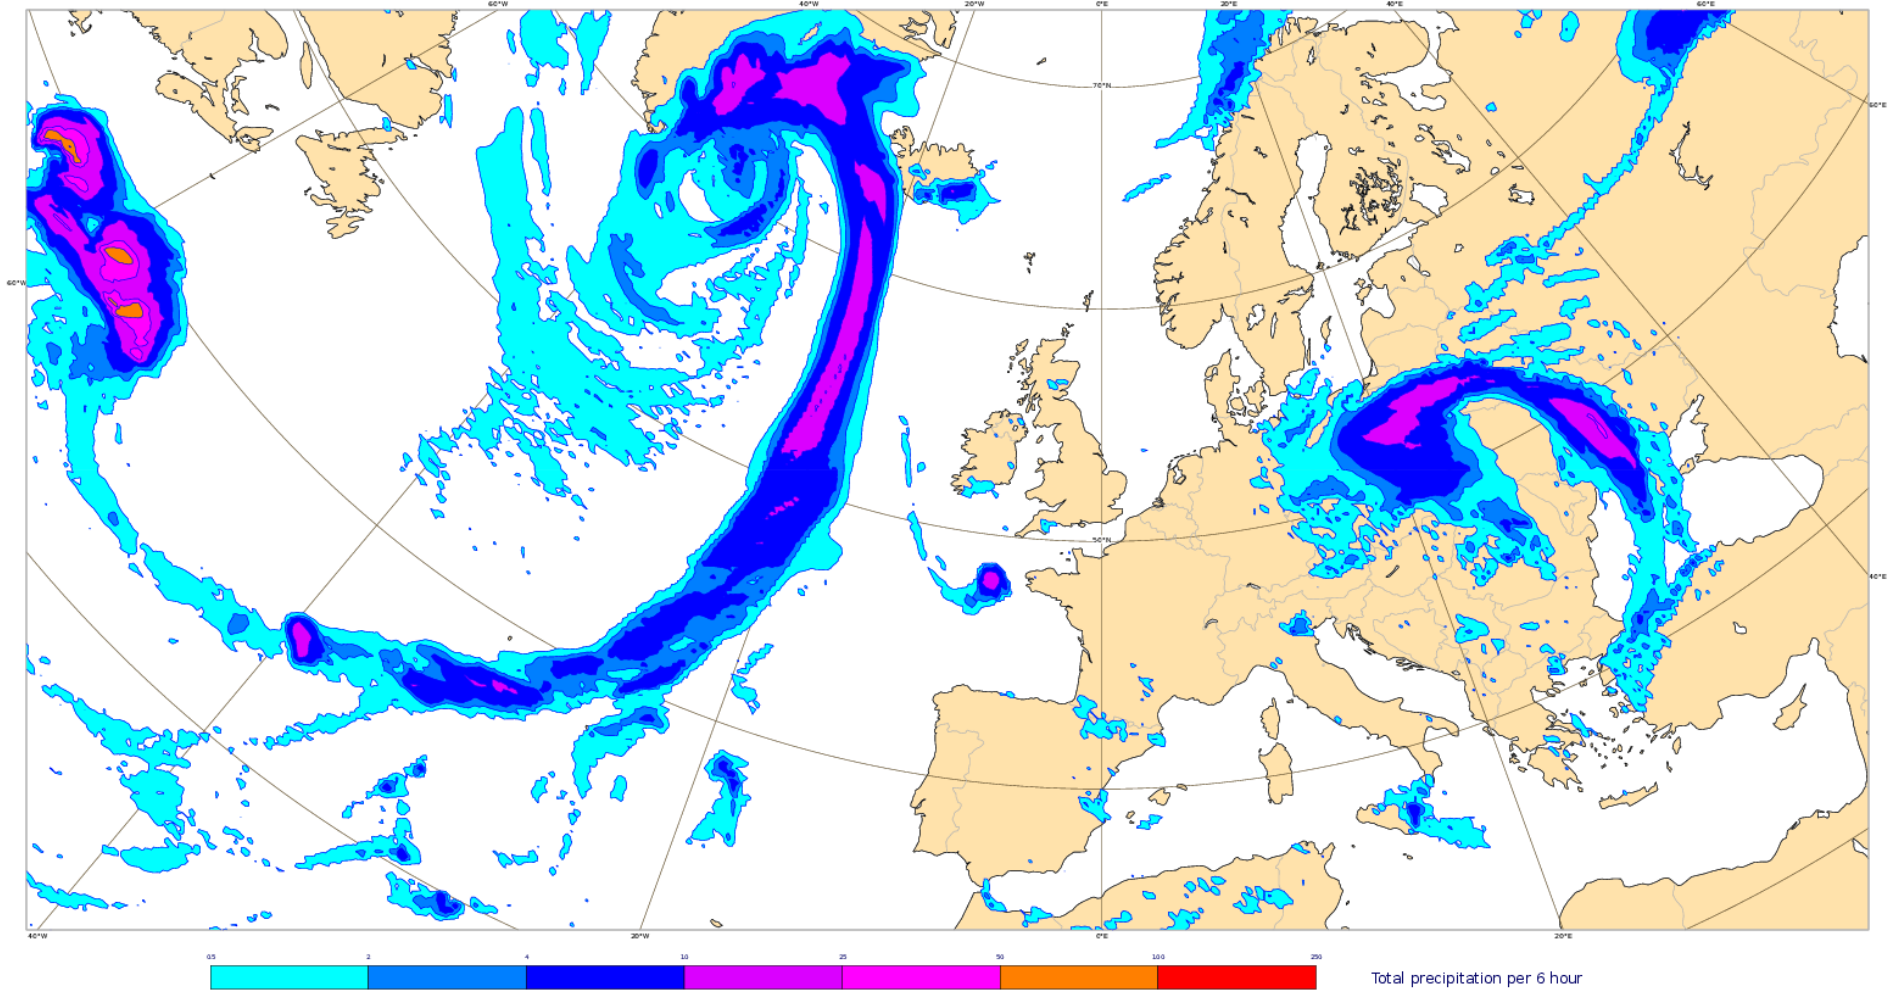

S stratiform cloud scheme

- 5 prognostic cloud variables + water vapour
- Ice and water independent variables
- Snow/rain prognostic, advected with the wind
- Physically based, increasing realism

Example 12 hour precipitation accumulation recast for Wed 5 October 2016

Untitled - Tuesday 4 Oct 2016, 00 UTC VT Wednesday 5 Oct 2016, 12 UTC Step 36
© ECMWF 2016

Precipitation Accumulation: Large-scale rain + convective rain + large-scale snow + convective snow

Example precipitation rate recast for Wed 5 October 2016 12Z

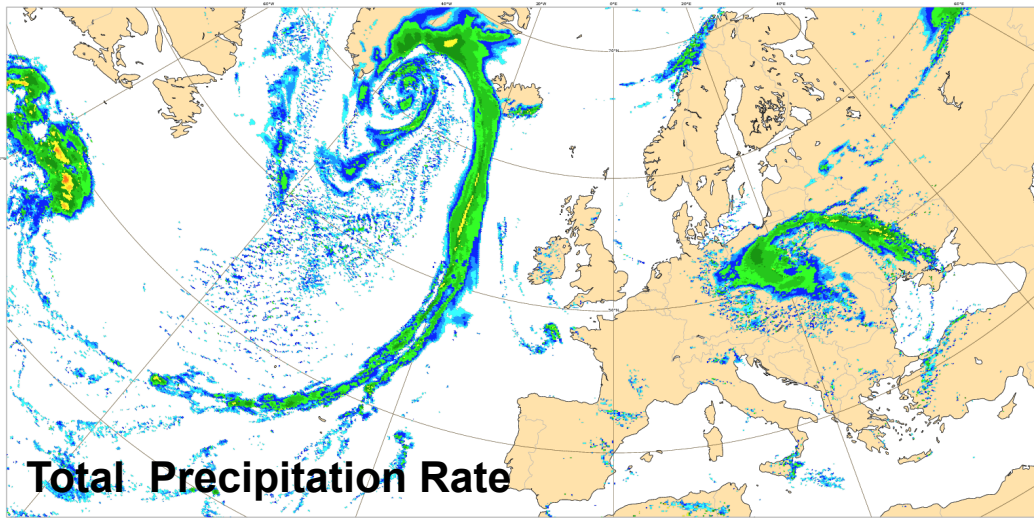

Untitled - Tuesday 4 Oct 2016, 00 UTC VT Wednesday 5 Oct 2016, 12 UTC Step 36

Convective precipitation rate

Cloud: 00Z Monday 27 January 2014

Meteosat IR 10.8μm

IFS Pseudo-IR 10.8μm

IFS cloud product (Low, Med, High and mixed)

Low L+M Medium M+H High H+L H+M+L clouds

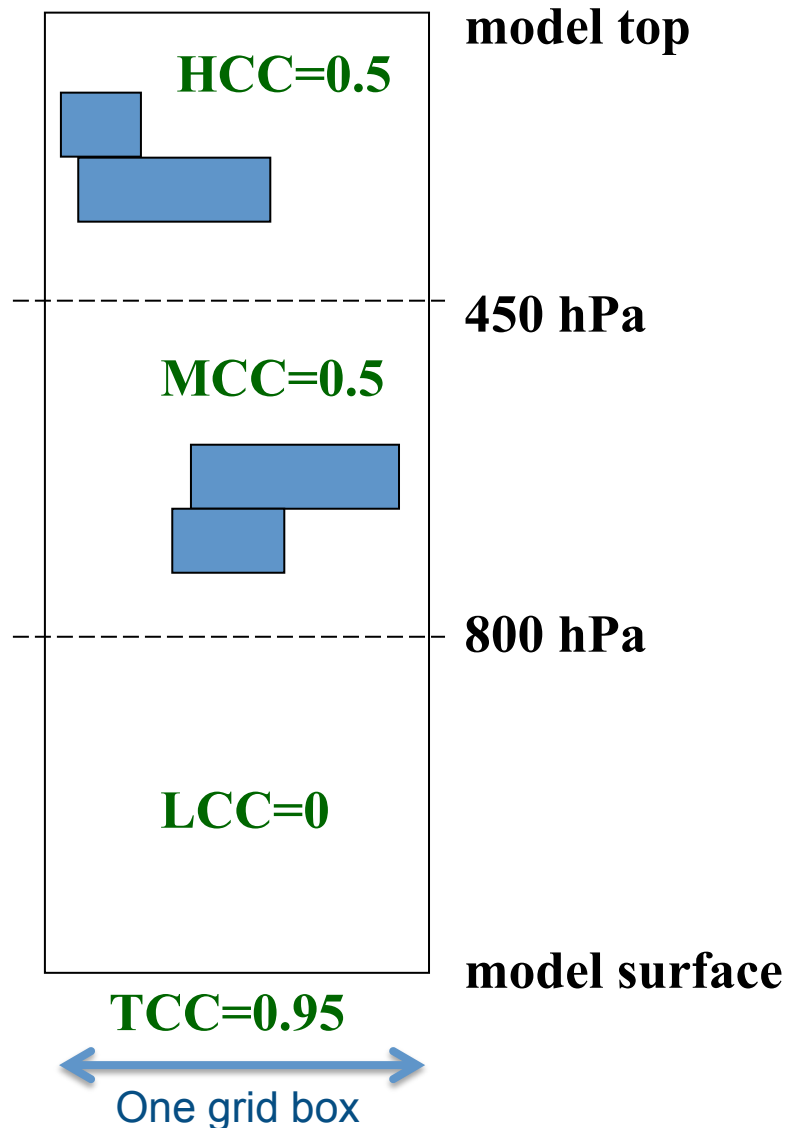

ECcharts IFS cloud product (Low, Med, High)

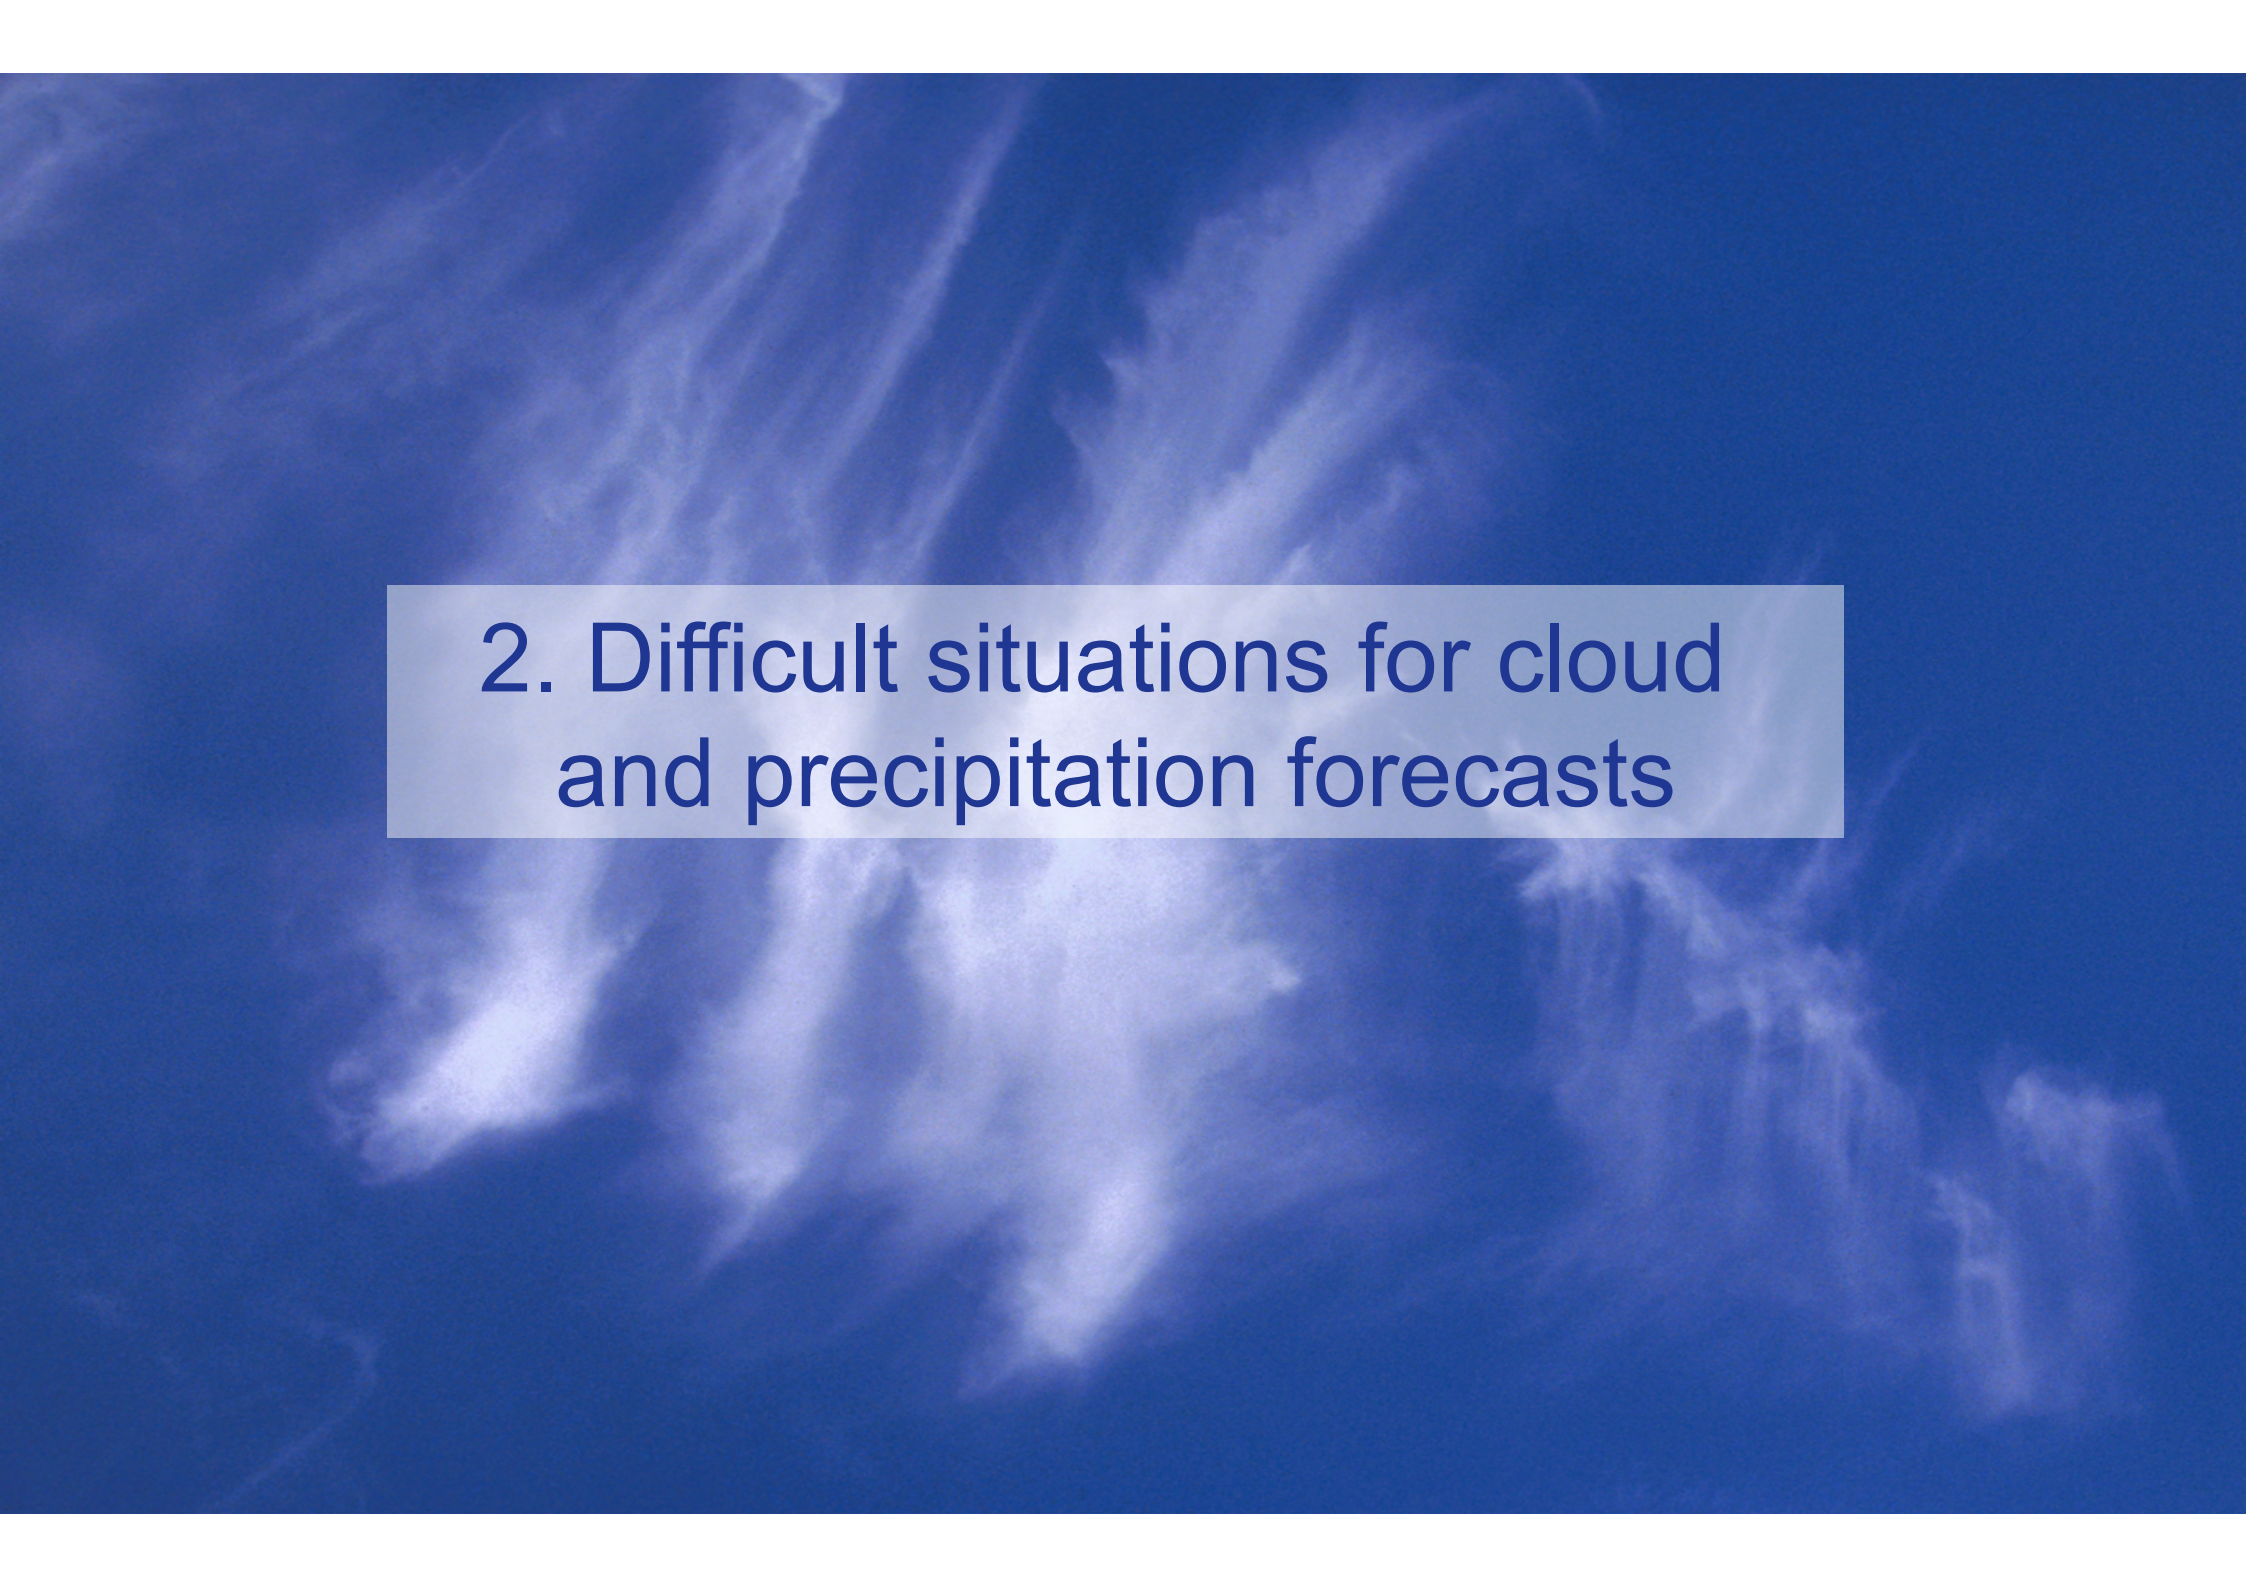

cloud overlap

Example

- TCC (total cloud cover). Model level clouds are integrated from surface to top of the atmosphere with overlap assumptions **based on global observations** (degree of randomness depends on distance between layers)
- HCC (high level cloud cover). Integrated from top to 450 hPa.
- MCC (medium level cloud cover). Integrated from 450 to 800 hPa.
- LCC (low level cloud cover). Integrated from 800 hPa to surface.
- $TCC \leq LCC + MCC + HCC$

2. Difficult situations for cloud and precipitation forecasts

Some of the difficult cloud problems for forecast models...

1. Boundary layer cloud (e.g. high pressure situations).
Impact on 2m temperatures.
2. Supercooled liquid topped boundary layer cloud.
Impact on 2m temperatures, particularly higher latitudes
3. Snowfall in marginal situations – the melting layer
4. Freezing rain
5. Fog

(1) Too little low cloud cover: Fog rising to stratocumulus example
Sounding Stuttgart 16 Nov, 2011
Too little cloud cover leads to warm bias in central Europe.

Obs Analysis

Obs Fc T+12h

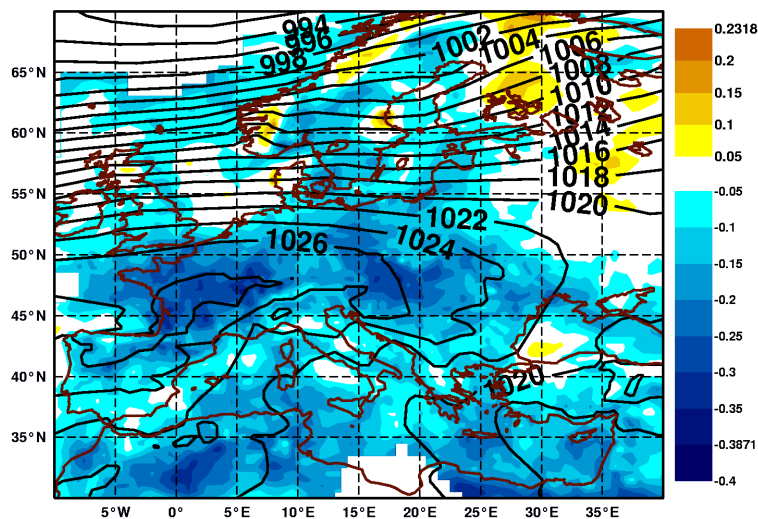

Fog rising developing into stratocumulus deck could not be properly represented

(1) Low cloud cover: 36h forecast versus SYNOP observation (for high pressure days over Europe during winter)

(4) Super-cooled liquid water

Commonly observed in the atmosphere

- Super-cooled liquid water (SLW) cloud frequently occurs in atmosphere as observed from aircraft & remote sensing.
- Radiatively important and can increase cloud lifetime (liquid drops suspended, ice crystals grow and fall out)
- Fine balance between turbulent production of water droplets, nucleation of ice, deposition growth and fallout.
- Difficult for models - uncertainties in turbulent mixing, ice microphysics, vertical resolution...
- Can impact 2m temperatures

(4) Mixed-phase cloud and recent IFS model changes

Arctic cloud case study (MPACE) – typical of SLW topped cloud with ice fallout

New cloud scheme (revised 37r3+) – SLW at cloud top with ice fallout as obs

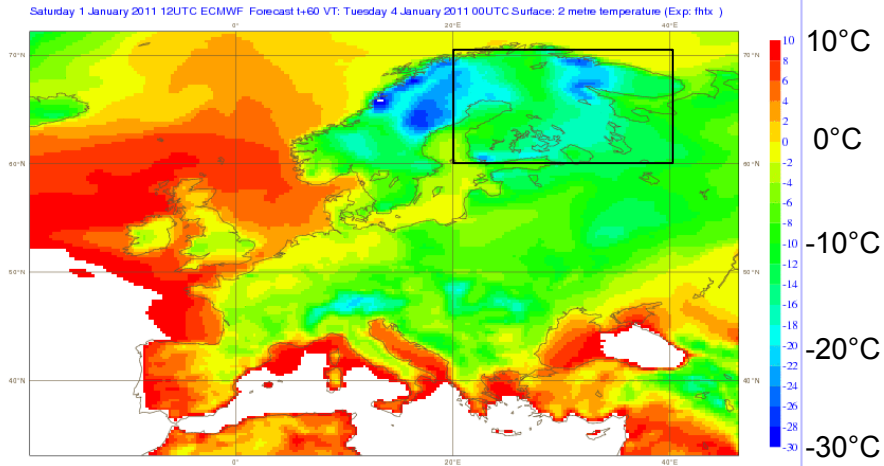

Forbes and Ahlgrimm (2014)

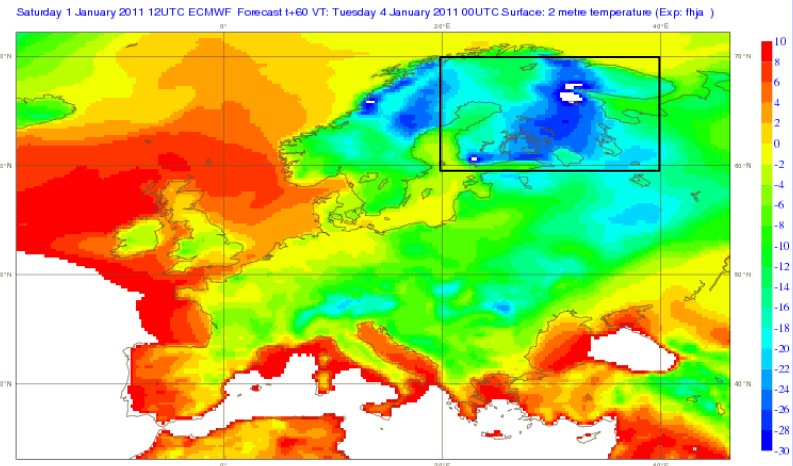

(4) Cold T2m bias in weakly forced mixed-phase

(Example T2mT snapshot from 00Z 4th Jan 2011 – Finland T bias)

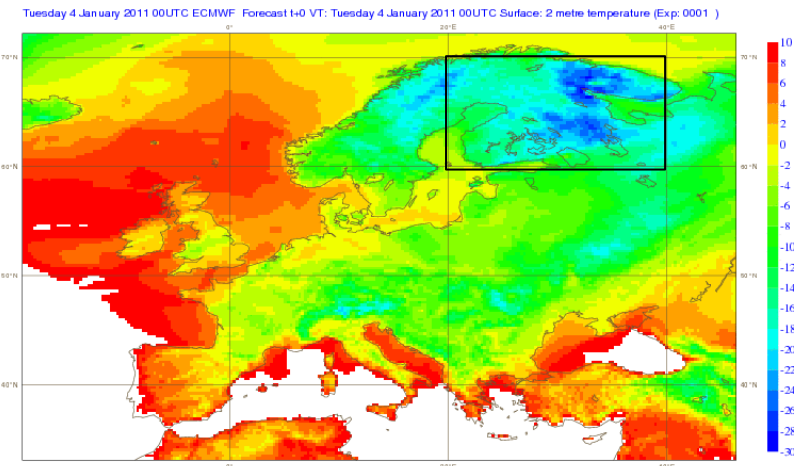

36r3 Diag mixed phase - 2009

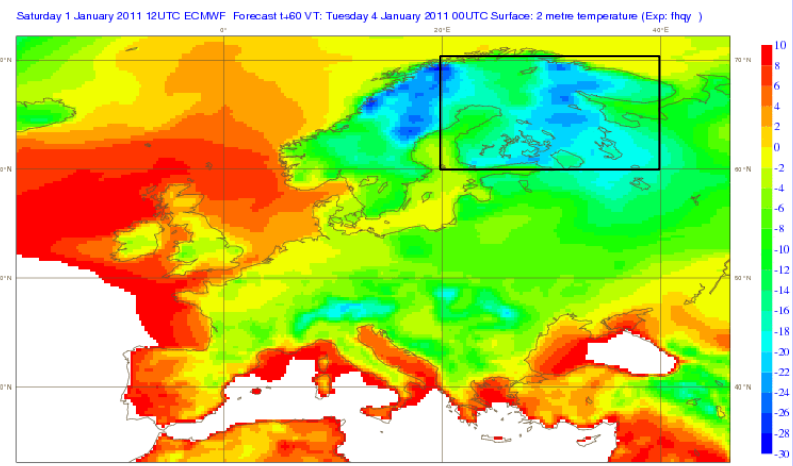

37r1 Prog mixed phase - 2010

Analysis

37r3 Prog mixed phase -2011/12

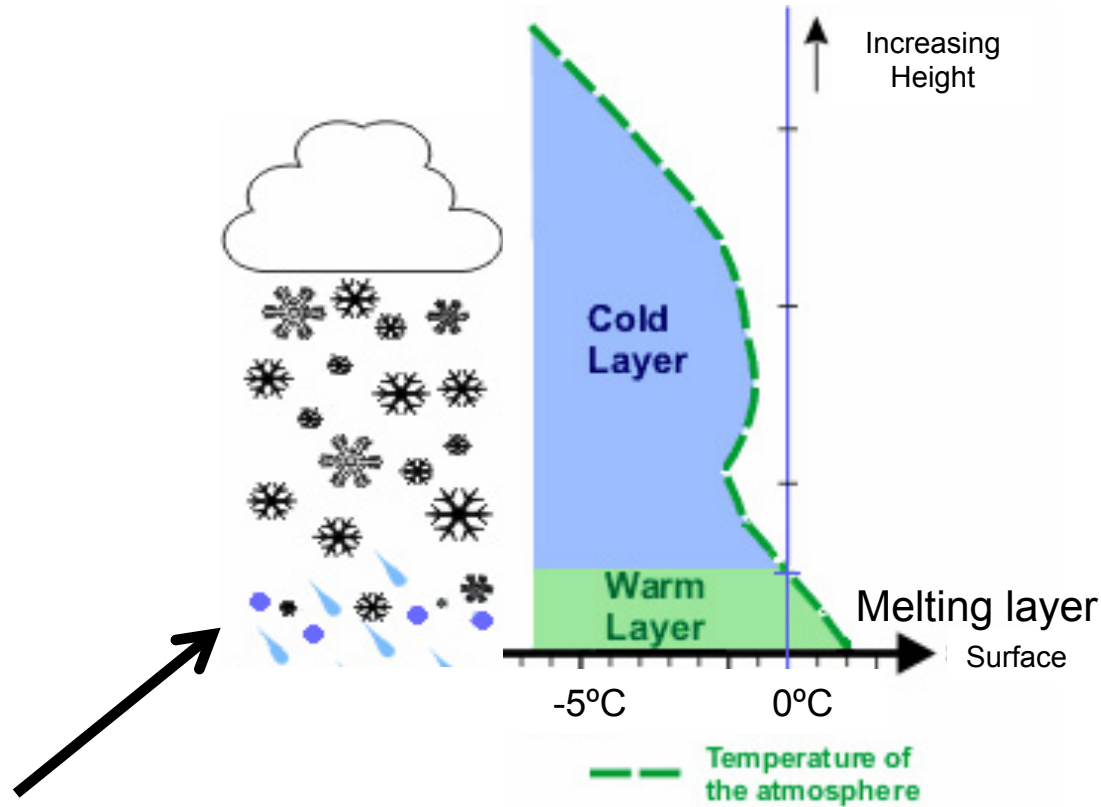

Snowfall in marginal situations

Snowfall in marginal situations: Melting layer

Melting layer often ~ few hundred metres thick

In drier air, snow melts at $T > 0^{\circ}\text{C}$ (due to evaporative cooling)

Sleet in melting layer:

Reality = melting particles, liquid surrounding an ice core

In the model = snow gradually transferred to rain variable

Snowfall in marginal situations: Ireland 01 Feb 2013

Snow depth forecast from basetime 12Z on 29 Jan

Snowfall in marginal situations

- Difficult to get right. A difference of 1 or 2°C makes all the difference between snowfall and rainfall (e.g. errors in large scale flow, surface too cold, precipitation rate incorrect)
- In the model, sleet (melting snow particles) is represented by a mix of rainfall and snowfall. Halfway through the melting layer will be 50% snowfall and 50% rainfall. NOTE: IFS diagnostics
 $TP = \text{totalprecip} = (\text{rainfall} + \text{snowfall})$, $SF = \text{snowfall}$
- Once on the ground and temperatures greater than zero, surface snow often takes too long to melt (recognised problem in the ECMWF model)

New (experimental) precipitation diagnostics (in Cy41r1)

- Precipitation type (valid at a particular time) (*ptype*)
 - (=1) Rain $T_{2m} > 0^{\circ}\text{C}$, liquid mass more than 80%
 - (=7) Mixed rain/snow $T_{2m} > 0^{\circ}\text{C}$, liquid mass $>20\%$ and $<80\%$
 - (=6) Wet snow $T_{2m} > 0^{\circ}\text{C}$, liquid mass less than 20%

 - (=5) Snow $T_{2m} < 0^{\circ}\text{C}$ “dry” snow
 - (=3) Freezing rain $T_{2m} < 0^{\circ}\text{C}$ supercooled rain from melted particles aloft
 - (=8) Ice pellets $T_{2m} < 0^{\circ}\text{C}$ refrozen from partially melted particles aloft

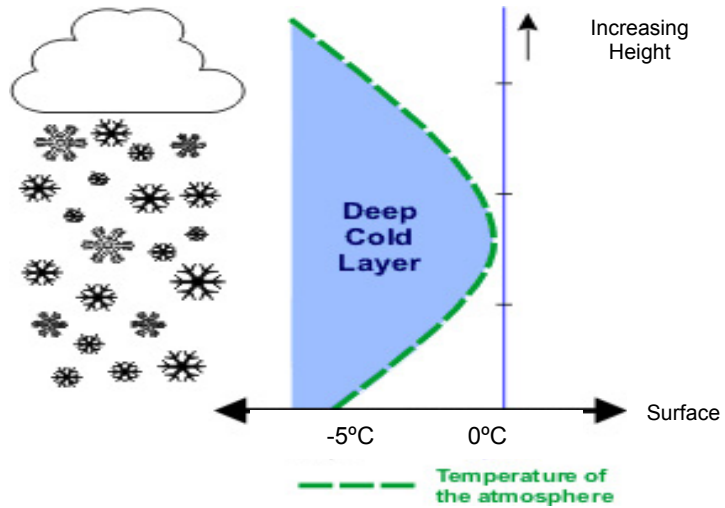

(Note: height of (uppermost) freezing level (*deg0l*) diagnostic also available)
(Graupel/Hail not available)
- Instantaneous precipitation rates (valid at a particular time)
 - Stratiform (large-scale) rainfall rate, and snowfall rate (*lsrr*, *lssfr*)
 - Convective rainfall rate, and snowfall rate (*crr*, *csfr*)
- Maximum and minimum total precipitation rates in the last 3 hours/6 hours/since last postprocessing time (*mintpr3*, *maxtpr3*, *mintpr6*, *maxtpr6*, *mintpr*, *maxtpr*)

Freezing Rain

Precipitation type – a new diagnostic from the IFS

rain / snow / wet snow / mix rain-snow / ice pellets / freezing rain

Snow

Sleet (melting snow) or rain

Freezing rain

Ice pellets

Predicting high-impact freezing rain events

Case Study: Slovenia/Croatia 02 Feb 2014

Freezing rain caused severe disruption and damage, transports/power/forests...

IFS physics at the time (40r1) not able to predict

New physics in 41r1 allows prediction of freezing rain events

Evaluation in HRES/ENS shows potential for useful forecasts

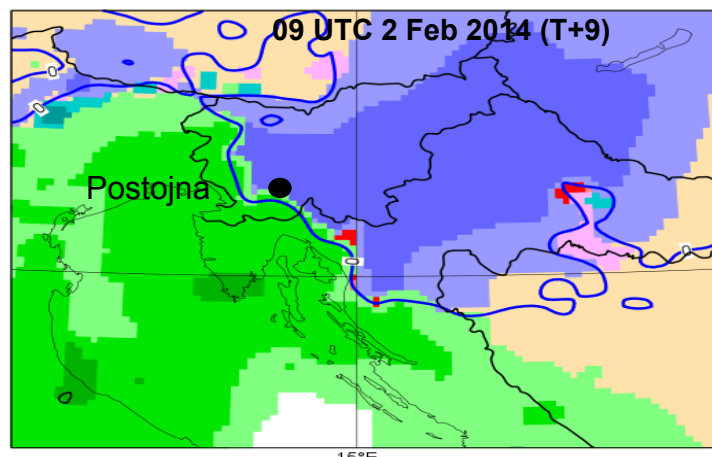

Article in EC Newsletter Autumn 2014 (but note results below are with new rain freezing physics)

Visibility and Fog

Prediction of severe weather: Visibility/Fog

Visibility – new diagnostic in IFS Cy41r1 (May 2015-)

Background **aerosol** seasonally varying climatology – currently Tegen et al. 1997

Rain and snow **precipitation**

Cloud liquid water/ice (i.e. **fog**)

Visibility is calculated using an exponential scattering law and a visual range defined by a fixed liminal contrast of 0.05 based on extinction due to clean air, aerosol, cloud and precipitation

Key limitations!

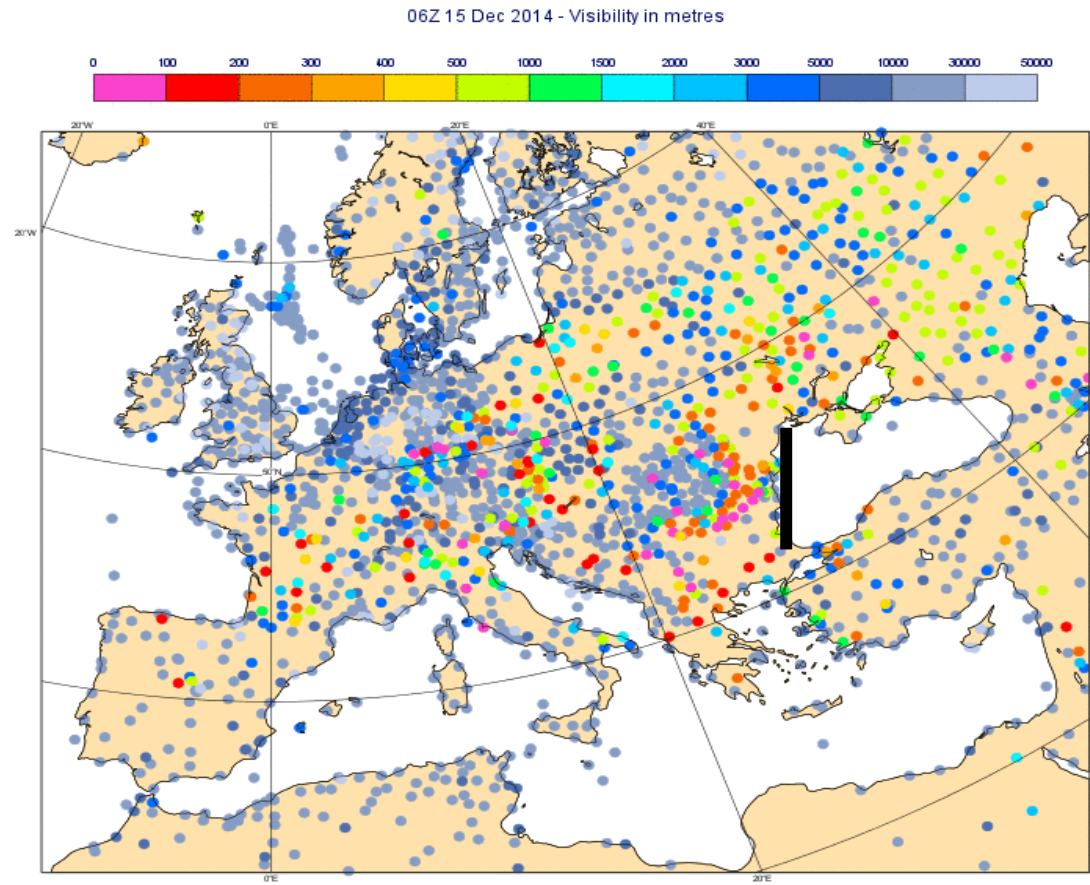

“Fixed aerosol” – will change to MACC-based aerosol climatology with RH-dependent size distribution. Use of prognostic aerosol in MACC at some point in the future...

Fixed particle size for cloud and precipitation particles (single moment microphysics), could introduce variable (diagnostic) particle size distributions

Relatively low resolution – orography, 10m lowest model level, correct physics??? (turbulence, microphysics, radiation interactions...)

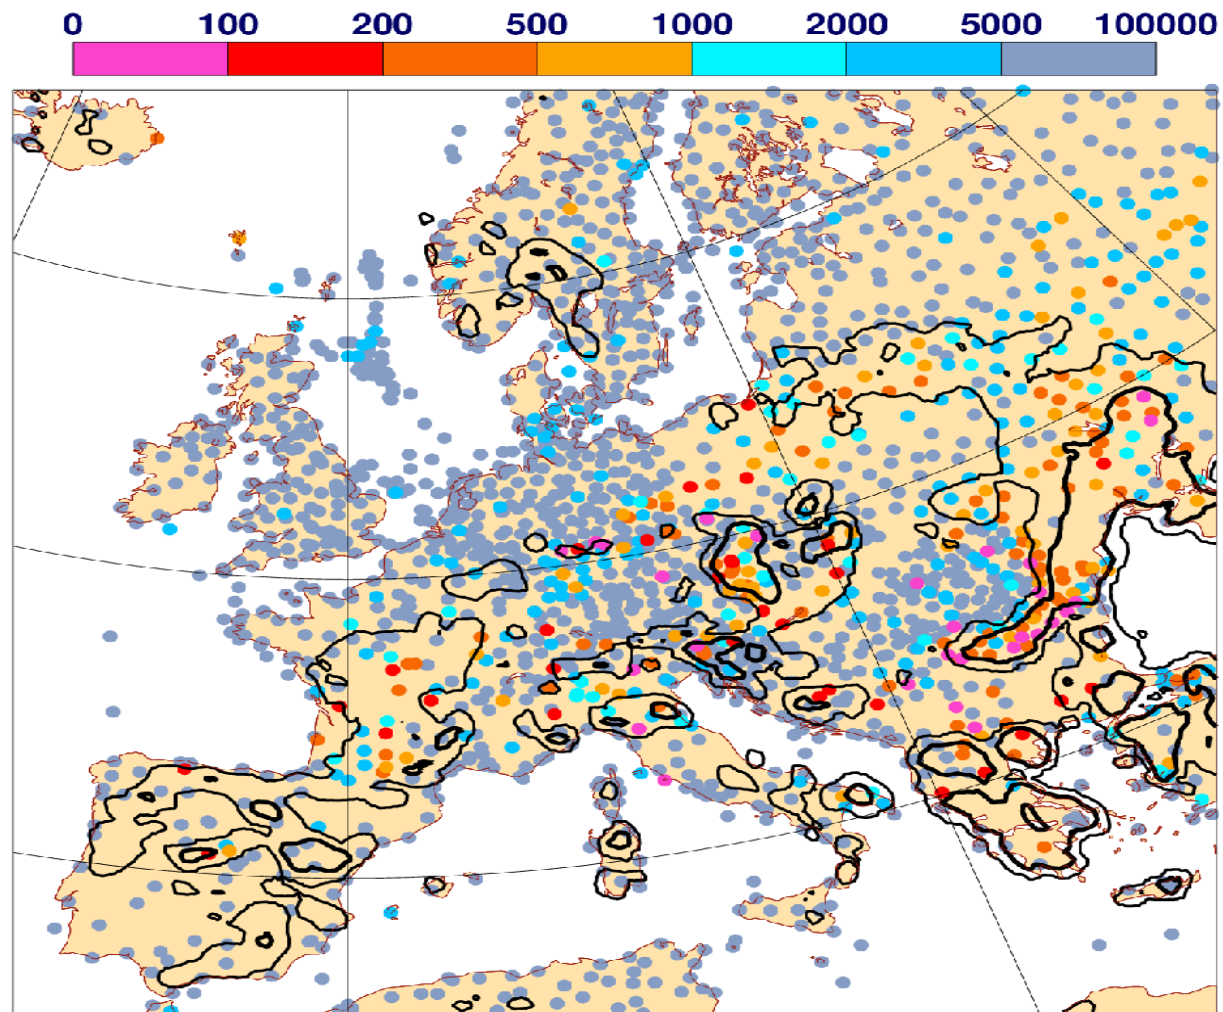

Prediction of severe weather: Visibility/Fog

Case study: 15 Dec 2014

Prediction of severe weather: Visibility/Fog

Case study: 15 Dec 2014, 3 day probability forecast from IFS ensemble

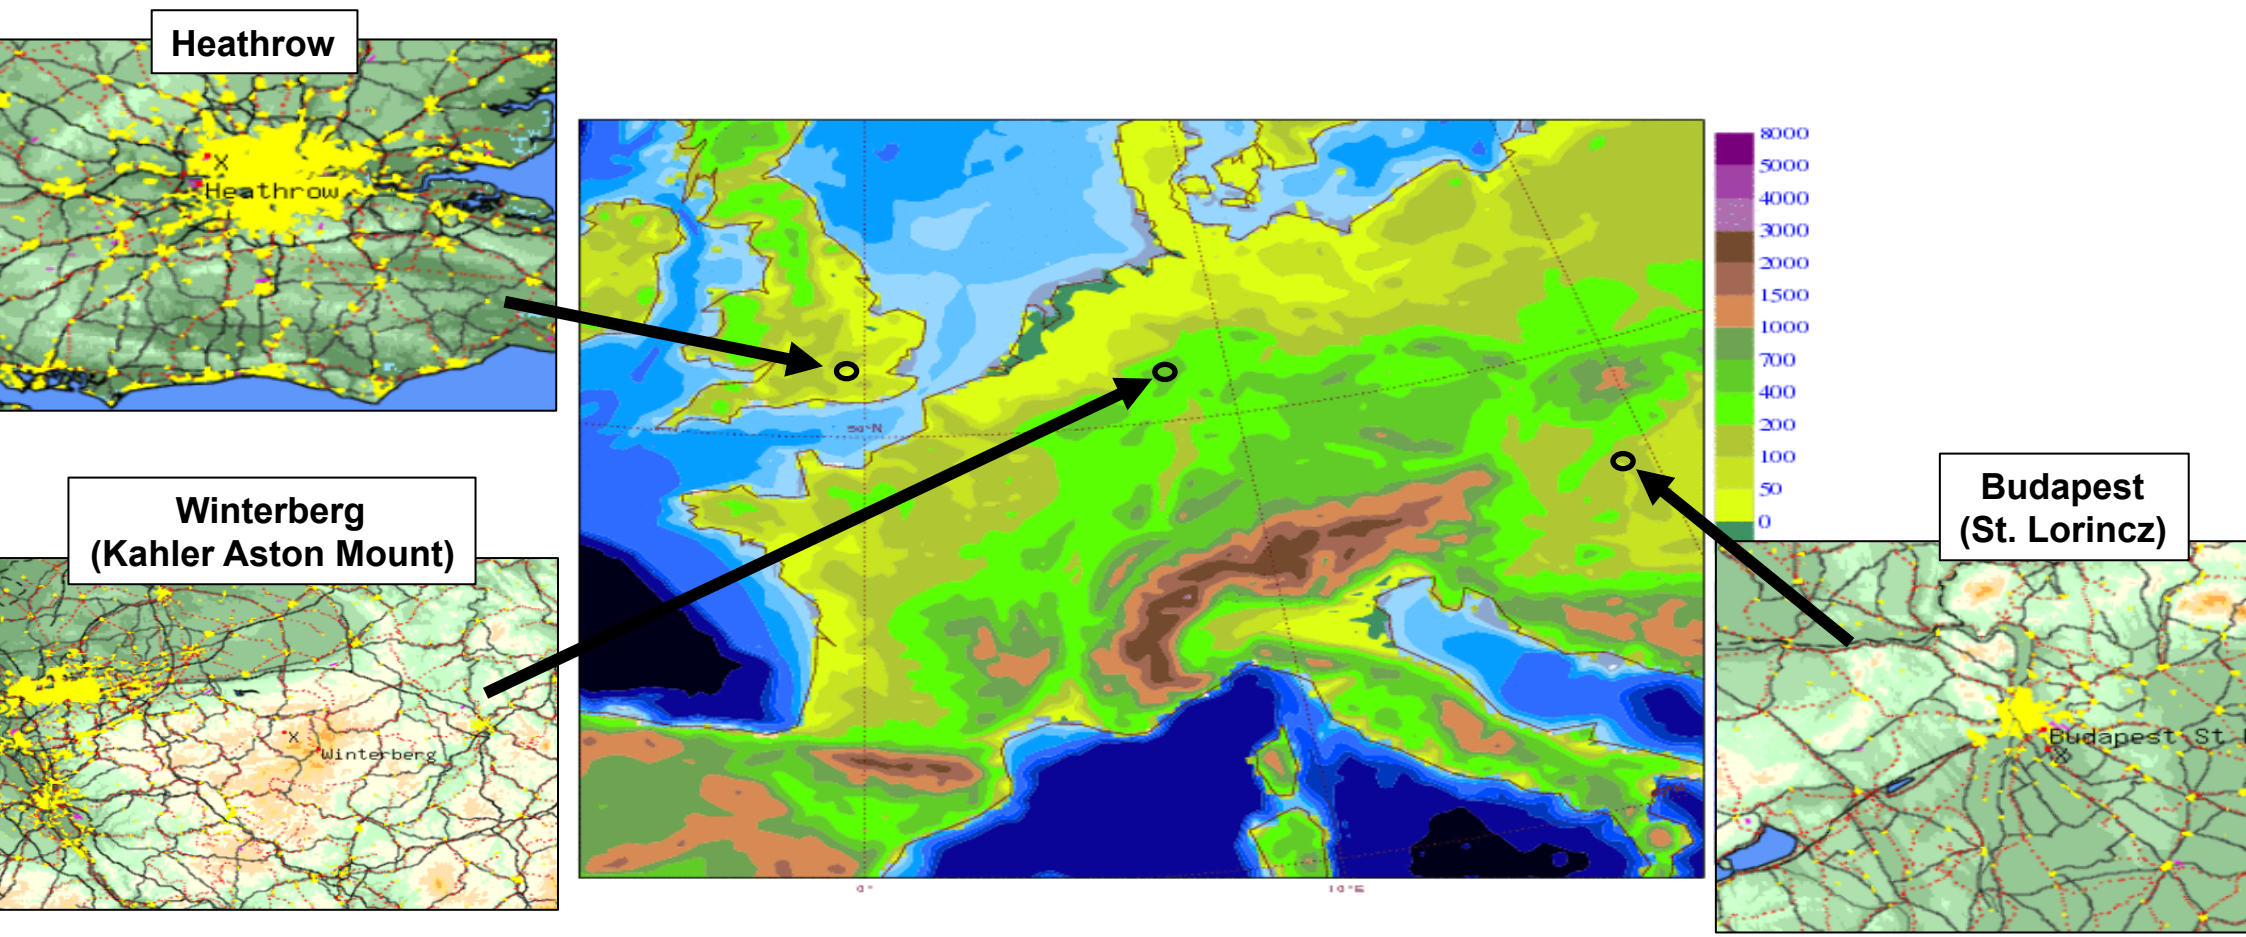

Observed visibility (m) at 06Z 15 Dec 2014 (dots)

ENS 3-day forecast probability of fog (<1000m) >10% (thin), >50% (thick)

Prediction of severe weather: Visibility/Fog

Prediction of severe weather: Visibility/Fog

Case study: 27 Oct 2015 - Fog in southern Sweden

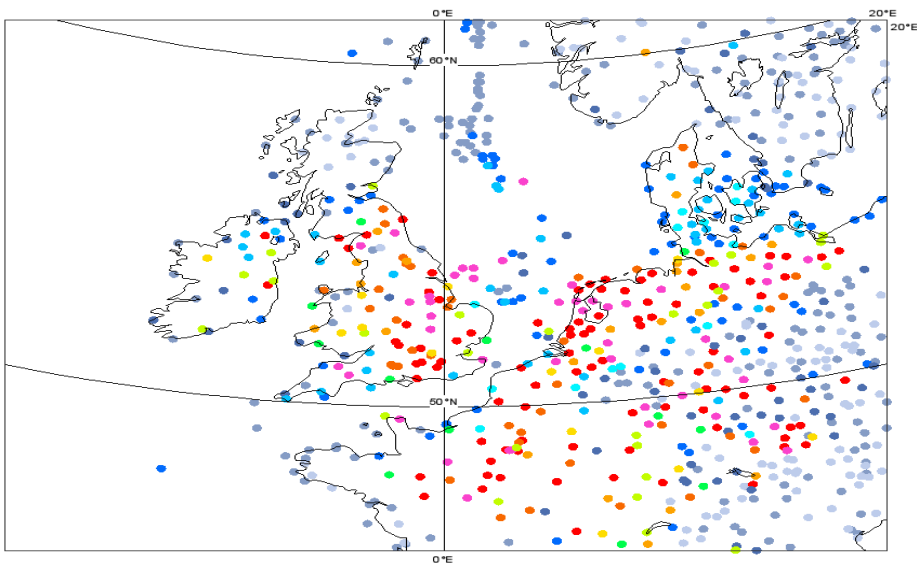

Onset well predicted by HRES, but clears too early

ENS shows spread early on but also doesn't capture the fog staying later in the day

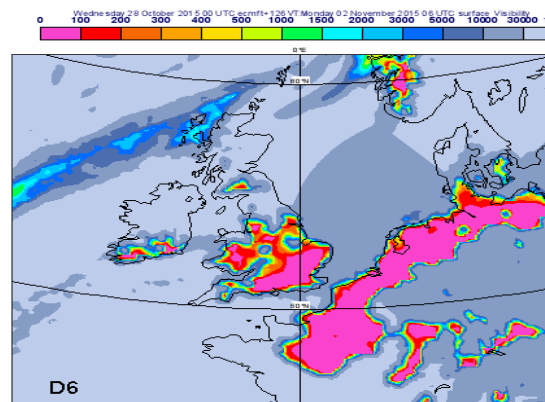

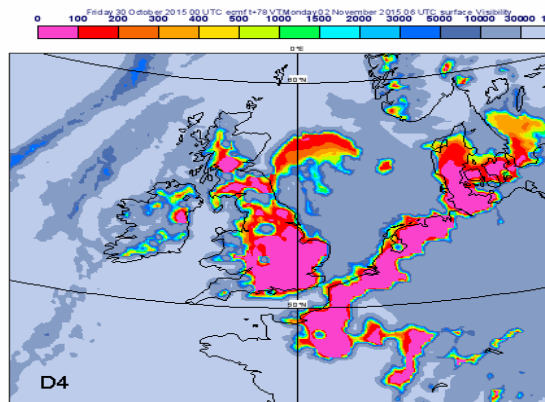

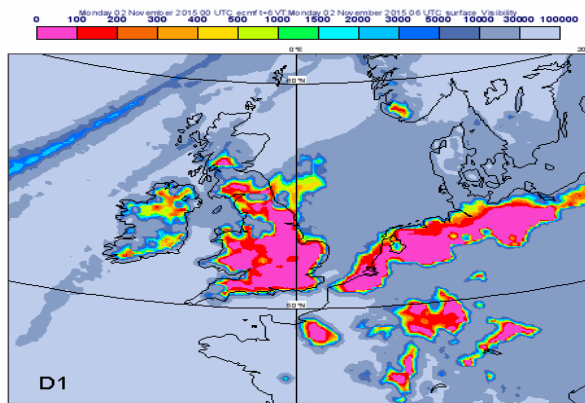

Prediction of severe weather: Visibility/Fog Case study: 02 Nov 2015

06Z 2 Nov 2015 - Visibility in metres

- In this case, indication of widespread fog event out to 6-day forecast
- Not always the case!
- Some regions missed
- Visibilities a bit too low in fog

A background image of a clear blue sky with scattered, wispy white clouds. The clouds are most prominent in the center and right side of the frame.

Summary

Improvement in cloud cover skill – the last decade

See also Haiden et al (2015) ECMWF Newsletter 14

Evolution of skill of the HRES forecast at day 5, expressed as relative skill (stdev) compared to ERA-Interim (12 month running mean)

What we covered...

1. Overview of parametrization of cloud and precipitation in the IFS
2. Some of the difficult “stratiform” cloud/precip regimes for the model – low cloud, mixed-phase, melting layer, fog
3. New diagnostics
 - Precipitation type – Melting snow, freezing rain
 - Visibility / fog (experimental)
 - Ensemble probabilities most useful in medium-range
 - Feedback welcome!!!

Thank you for listening! Questions? Feedback?
