Introduction

The following procedures describe how to compute the pressure and geopotential on model levels, geopotential height and geometric height.

Pressure on model levels

In ERA5, pressure is provided at the surface, but not on individual model levels. However, an illustration of pressure on model levels (`p_ml`) is shown in Figure 1, and the pressure can be computed for particular dates and times using the procedure described below.

You will need the following inputs:

- logarithm of surface pressure (`lnsp`)

Example to download ERA5 `lnsp` data for a given area at a regular lat/lon grid in NetCDF format

```
#!/usr/bin/env python
import cdsapi
c = cdsapi.Client()
c.retrieve('reanalysis-era5-complete', { # Requests follow MARS syntax
    # Keywords 'expver' and 'class' can be dropped. They are
    # since their values are imposed by 'reanalysis-era5-complete'
    # The hyphens can be omitted
    # 1 is top level, 137 the lowest model level in ERA5. Use '//'
    'date' : '2013-01-01',
    'levelist': '1',
    to separate values.
    'levtype' : 'ml',
    'param' : '152',
    db/
    # Full information at https://apps.ecmwf.int/codes/grib/param-
    # The native representation for temperature is spherical
    harmonics
    'stream' : 'oper',
    'time' : '00/to/23/by/6',
    of '00/06/12/18'
    'type' : 'an',
    'area' : '80/-50/-25/0',
    'grid' : '1.0/1.0',
    Gaussian grid
    'format' : 'netcdf',
    combination with 'grid'
}, 'ERA5-ml-1nsp-subarea.nc') # Output needs to be regular lat-lon, so only works in
# Output file. Adapt as you wish.
```

- $a(n)$ and $b(n)$ coefficients defining the model levels; these are included in the GRIB header of each model level GRIB message and are also tabulated [here](#).

The model half-level pressure (p_{half}), illustrated in Figure 2, is given by:

$$[\text{ \text{p_half} = a + b \text{last \text{sp}} }]$$

where sp ($(\text{ \text{sp}} = e^{\ln \text{sp}})$) is the surface pressure (and $\ln \text{sp}$ is its natural logarithm).

The pressure on model levels (p_{ml}), illustrated in Figure 1, is given by the mean of the pressures on the model half levels immediately above and below (see Figure 2):

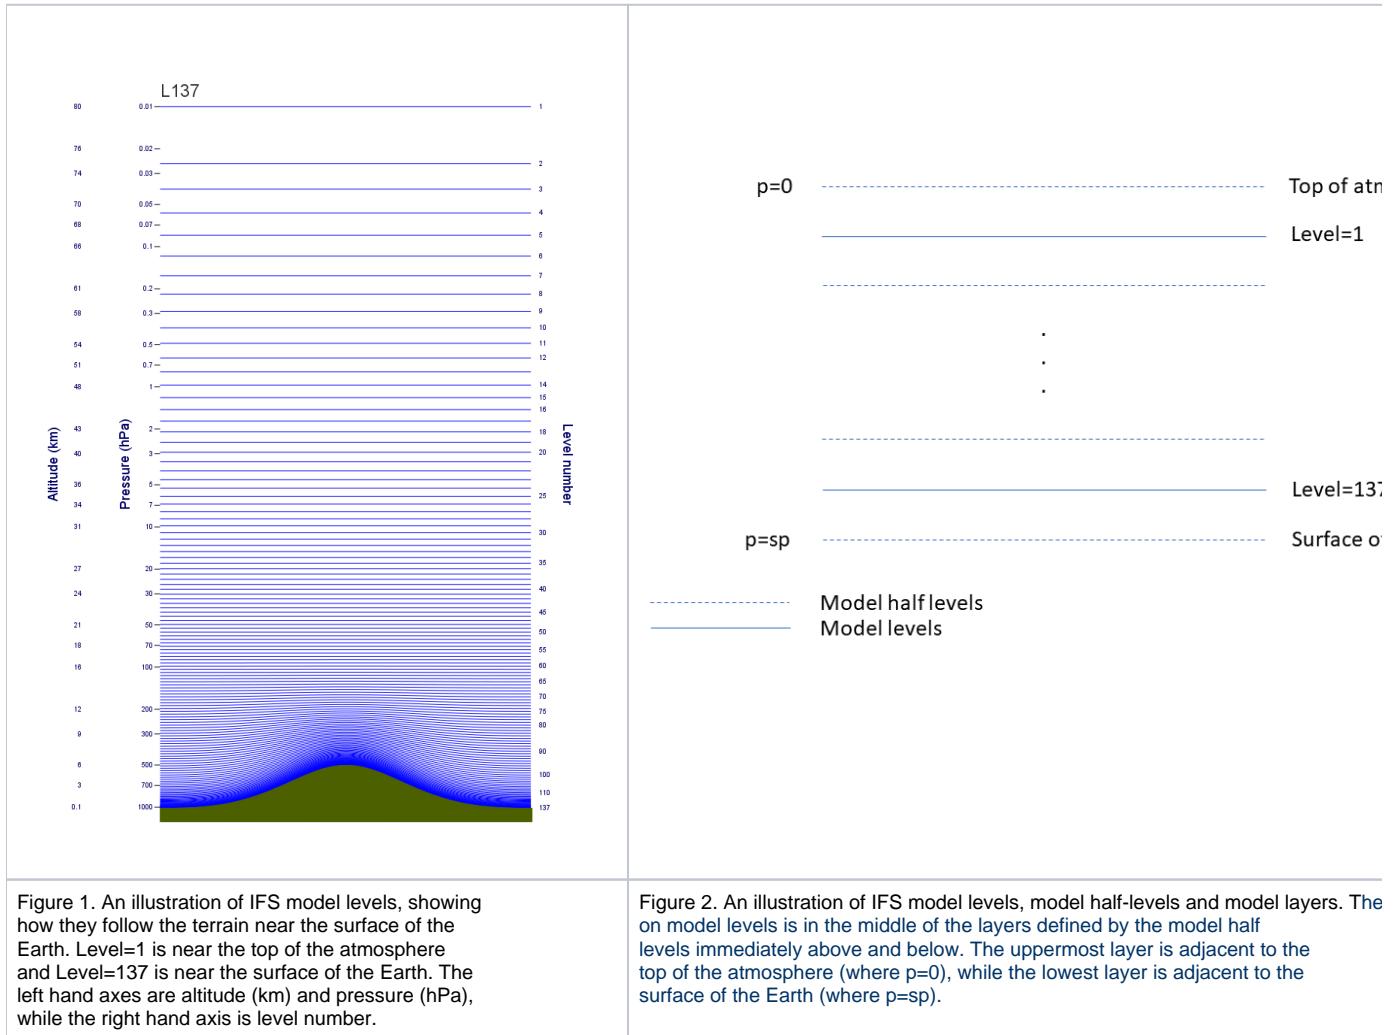

$$[\text{ \text{p_ml} = \frac{1}{2}(\text{p_half_above} + \text{p_half_below}) }]$$

This means that the pressure on model levels is in the middle of the layers defined by the model half levels (Figure 2).

For more details about the vertical discretisation in the ECMWF Integrated Forecasting System (IFS), please see [Part-iii Dynamics and numerical procedures, section 2.2](#) and the FULL-POS documentation at:

<http://www.umr-cnrm.fr/gmapdoc/spip.php?article157>

Illustrations of model levels, model half levels and model layers

Geopotential on model levels

In ERA5, geopotential (z) is provided at the surface, but not on individual model levels. However, geopotential on model levels can be computed using the procedure described below.

Inputs:

- geopotential at the surface
- logarithm of surface pressure (lnsp)
- temperature and specific humidity on all the model levels

Output: Geopotential for each level, in m^2/s^2 .

In the procedure below, the output data is written in GRIB format.

Please note, this procedure is an approximation to the calculation performed in the IFS (which also takes account of the effects of cloud ice and water and rain and snow).

Prerequisites to calculating Geopotential on model levels

You will need:

- A computer running Linux
- Python3
- The CDS API installed; Your computer must be set up for downloading ERA5 model level data (from the 'reanalysis-era5-complete' dataset, stored in ECMWF's MARS catalogue) through the CDS API. For more details, please [follow the instructions here](#) (step B).
- The `ecCodes` library to read and write data.

Step 1: Download input data

First we must retrieve the required ERA5 data. We need:

- Temperature (t) and specific humidity (q) on each model level.
- The logarithm of surface pressure (lnsp) and geopotential (z) on model level 1.

We use a Python script to download the ERA5 data from the MARS catalogue using the CDS API. The procedure is:

1. Copy the script below to a text editor on your computer
2. Edit the date, type, step, time, grid and area in the script to meet your requirements
3. Save the script (for example with the filename as 'get_data_geopotential_on_ml.py')
4. Run the script

Python script to download ERA5 data NOT listed in CDS through CDS API

```
#!/usr/bin/env python
import cdsapi
c = cdsapi.Client()

# data download specifications:
cls      = "ea"          # do not change
expver   = "1"           # do not change
levtype  = "ml"          # do not change
stream   = "oper"        # do not change
date     = "2018-01-01"    # date: Specify a single date as "2018-01-01" or a period as "2018-08-01/to/2018-01-31".
For periods > 1 month see https://confluence.ecmwf.int/x/17GqB
tp       = "an"          # type: Use "an" (analysis) unless you have a particular reason to use "fc" (forecast).
time    = "00:00:00"      # time: ERA5 data is hourly. Specify a single time as "00:00:00", or a range as "00:00:00/01:00:00/02:00:00" or "00:00:00/to/23:00:00/by/1".

c.retrieve('reanalysis-era5-complete', {
    'class'    : cls,
    'date'     : date,
    'expver'   : expver,
    'levelist': '1/2/3/4/5/6/7/8/9/10/11/12/13/14/15/16/17/18/19/20/21/22/23/24/25/26/27/28/29/30/31/32/33/34/35
/36/37/38/39/40/41/42/43/44/45/46/47/48/49/50/51/52/53/54/55/56/57/58/59/60/61/62/63/64/65/66/67/68/69/70/71/72
/73/74/75/76/77/78/79/80/81/82/83/84/85/86/87/88/89/90/91/92/93/94/95/96/97/98/99/100/101/102/103/104/105/106
/107/108/109/110/111/112/113/114/115/116/117/118/119/120/121/122/123/124/125/126/127/128/129/130/131/132/133/134
/135/136/137',      # For each of the 137 model levels
    'levtype' : 'ml',
    'param'   : '130/133', # Temperature (t) and specific humidity (q)
    'stream'  : stream,
    'time'    : time,
    'type'    : tp,
    'grid'    : [1.0, 1.0], # Latitude/longitude grid: east-west (longitude) and north-south resolution
(latitude). Default: 0.25 x 0.25
    'area'    : area, #example: [60, -10, 50, 2], # North, West, South, East. Default: global
}, 'tq_ml.grib')

c.retrieve('reanalysis-era5-complete', {
    'class'    : cls,
    'date'     : date,
    'expver'   : expver,
    'levelist': '1',       # Geopotential (z) and Logarithm of surface pressure (lnsp) are 2D fields, archived
as model level 1
    'levtype' : levtype,
    'param'   : '129/152', # Geopotential (z) and Logarithm of surface pressure (lnsp)
    'stream'  : stream,
    'time'    : time,
    'type'    : tp,
    'grid'    : [1.0, 1.0], # Latitude/longitude grid: east-west (longitude) and north-south resolution
(latitude). Default: 0.25 x 0.25
    'area'    : area, #example: [60, -10, 50, 2], # North, West, South, East. Default: global
}, 'zlnsp_ml.grib')
```

Running the script produces two new files in the current working directory:

- 'tq_ml.grib' (a GRIB file containing temperature and specific humidity)
- 'zlnsp_ml.grib' (a GRIB file containing geopotential and log of surface pressure).

Step 2: Compute geopotential on model levels

We then use a Python script to compute geopotential (z) for all model levels:

1. Copy the script below to a text editor
2. Save the script as 'compute_geopotential_on_ml.py'
3. Run the script 'compute_geopotential_on_ml.py' with the correct arguments, i.e.: `python compute_geopotential_on_ml.py tq_ml.grib zlnsp_ml.grib -o z_on_ml.grib`

```

#!/usr/bin/env python3

Category      : COMPUTATION

OneLineDesc   : Computes geopotential on model levels

Description   : Computes geopotential on model levels.
                Based on code from Nils Wedi, the IFS documentation:
                https://software.ecmwf.int/wiki/display/IFS/CY41R1+Official+IFS+Documentation
                part III. Dynamics and numerical procedures
                optimised implementation by Dominique Lucas.
                ported to Python by Cristian Simarro

Parameters    : tq.grib           - grib file with all the levelist
                zlnsp.grib        - grib file with levelist 1 for params
                z and lns
                -l levelist (optional) - slash '/' separated list of levelist
                                         to store in the output
                -o output (optional) - name of the output file
                                         (default='z_out.grib')

Return Value  : output (default='z_out.grib')
                A fieldset of geopotential on model levels

Dependencies  : None

Example Usage :
                  compute_geopotential_on_ml.py tq.grib zlnsp.grib
'''

```

This script is from ECMWF's generic article [Compute geopotential on model levels](#).

Alternatively, there is a customer-supplied script (which runs on Microsoft Windows) that computes geopotential on model levels for a specific location. This script was written for the ERA-Interim dataset, but can be adapted to ERA5. Please see the article [ERA-Interim: compute geopotential on model levels](#) for details.

For users experienced in [Metview](#), there is a built-in function called [mvl_geopotential_on_ml](#).

Interpolation of variables from model levels to custom pressure levels

The procedure described below is to convert ERA5 model levels data to custom pressure levels data.

Input:

- variable(s) on model levels and related logarithm surface pressure in grib format
- list of custom pressure levels required for interpolation to.

Output: NetCDF file containing variable(s) at each custom pressure level

Prerequisites for interpolating variables on model levels to custom pressure levels

You will need:

- Python3
- The CDS API **installed**. For more details, please [follow the instructions here](#).
- The **ecCodes** library to read and write data.

Step 1: Download input data

First the required ERA5 variable(s) on model levels data are downloaded. The suggested procedure is:

1. Copy the script below to a text editor on your computer
2. Edit the date, type, step, time and grid in the script to meet your requirements. Note the 'area' keyword can also be used. The output filename can be modified accordingly.
3. Save the script (for example with the filename as 'get_data.py')
4. Run the script i.e. `python3 get_data.py`

get_data

import cdsapi

c = cdsapi.Client()

c.retrieve('reanalysis-era5-complete', {
    'class': 'ea',
    'date': '2021-01-01',
    'expver': '1',
    'levelist':'1/to/137',
    'levtype': 'ml',
    'param': '130/152',
    'step': '0',
    'stream': 'oper',
    'time': '00/to/06/by/1',
    'type': 'an',
    'grid': '1.0/1.0'
}, 'output_00_06_130_152_1x1.grib')
```

Running the script produces a file in the current working directory called 'output_00_06_130_152_1x1.grib' (a GRIB file containing the ERA5 variables needed.).

Step 2: Interpolate variables on model levels to custom pressure levels

The suggested procedure to run the Python script to compute the conversion of the variable from model levels to the custom pressure level is:

1. Copy the script below to a text editor
2. Save the script as 'conversion_from_ml_to_pl.py'
3. Run the script 'conversion_from_ml_to_pl.py' with the correct arguments, i.e.: `python3 conversion_from_ml_to_pl.py -p 70000 -o output.nc -i output_00_06_130_152_1x1.grib`

conversion_from_ml_to_pl.py

```

This produces a netCDF file called 'output.nc' in the current directory containing the interpolated data.

Geopotential height

In ERA5 (and in the IFS), and often in meteorology, heights (the height of the land and sea surface, or specific heights in the atmosphere) are not represented as geometric height, or altitude (in metres above the spheroid), but as geopotential height (in geopotential metres above the geoid). Note, that ECMWF usually archives the geopotential (in m^2/s^2), not the geopotential height.

To obtain the geopotential height (h) in (geopotential) metres (of the land and sea surface or at particular heights in the atmosphere), simply divide the geopotential by the Earth's gravitational acceleration, which has a fixed value of 9.80665 m/s^2 in the IFS. This geopotential height is relative to the geoid (over ocean, mean sea level is assumed to be coincident with the geoid) - for more information see [ERA5: data documentation - spatial reference systems](#).

Geometric height

Geometric height is not represented in ERA5 (nor in the IFS). However, the geometric height or altitude (alt) can be approximated by the following formula (neglecting horizontal variations in the Earth's gravitational acceleration):

$$\text{alt} = \text{Re} \cdot \text{ast} \cdot h / (\text{Re} - h)$$

where Re is the radius of the Earth, and h is the Geopotential height. This geometric height is relative to the geoid (over ocean, mean sea level is assumed to be coincident with the geoid) and it is assumed that the Earth is a perfect sphere - for more information see [ERA5: data documentation - spatial reference systems](#).
